Relational Data Model

Outline

1. Relational Data Model

2. From ER Diagrams to Relational Schema

3. Relational Operations

Relational Data Model

Key concept:

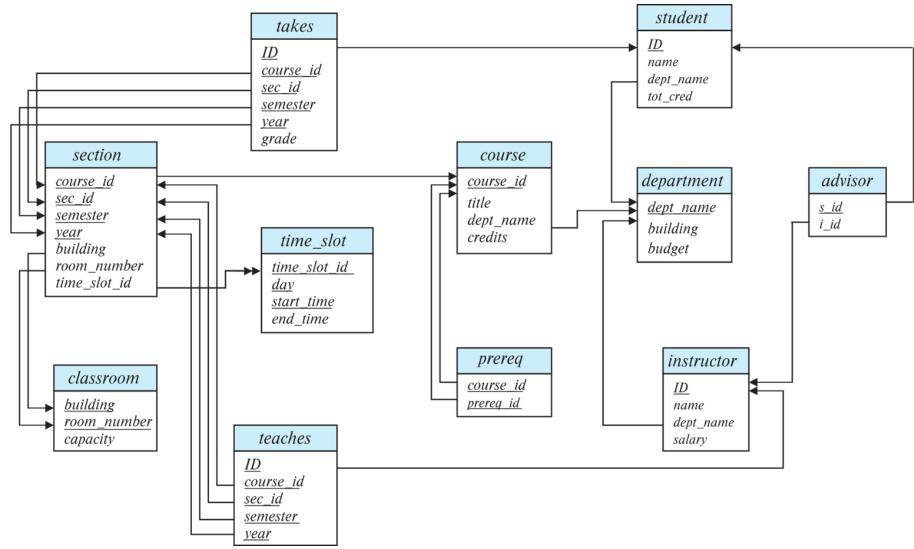

In ER both *Entity sets* and *Relationships* become relations (tables in RDBMS)

- Database schema is the logical structure of the database.
- Database instance is a snapshot of the data in the database at a given instant in time.

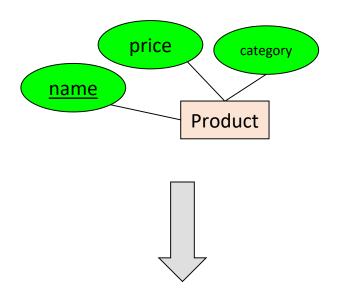

Keys

- Let $K \subseteq R$, K is a **superkey** of R if values for K are sufficient to identify a unique tuple of each possible relation r(R)
 - Example: {ID} and {ID,name} are both superkeys of instructor.
- Superkey K is a candidate key if K is minimal
 - Example: {ID} is a candidate key for Instructor
- One of the candidate keys is selected to be the primary key.
 - Which one?
- Foreign key constraint: Value in one relation must appear in another
 - Referencing relation
 - Referenced relation
 - Example: dept_name in instructor is a foreign key from instructor referencing department

Schema Diagram for University Database

From ER Diagrams to Database Instance

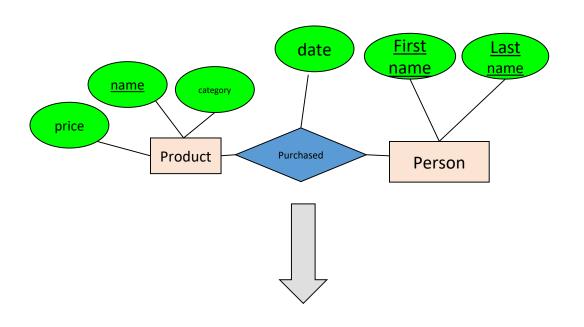

Product(name: string, price: double, category: string)

```
CREATE TABLE Product(
name CHAR(50) PRIMARY KEY,
price DOUBLE,
category VARCHAR(30)
)
```

Product

<u>name</u>	price	category
Gizmo1	99.99	Camera
Gizmo2	19.99	Edible

From ER Diagrams to Database Instance

Product(name:string, price: double, category: string)

Person(<u>firstname</u>: string, <u>lastname</u>: string)

Purchased(name: sting, firstname: string, lastname: string, date: date)

```
CREATE TABLE Purchased(
name CHAR(50),
firstname CHAR(50),
lastname CHAR(50),
date DATE,
PRIMARY KEY (name, firstname,
lastname),
FOREIGN KEY (name)
REFERENCES Product,
FOREIGN KEY (firstname, lastname)
REFERENCES Person
)
```

Purchased

<u>name</u>	<u>firstname</u>	<u>lastname</u>	date
Gizmo1	Bob	Joe	01/01/15
Gizmo2	Joe	Bob	01/03/15
Gizmo1	JoeBob	Smith	01/05/15

Reduction to Relation Schemas

- Entity sets and relationship sets can be expressed uniformly as *relation schemas* that represent the contents of the database.
- A database which conforms to an ER diagram can be represented by a collection of schemas.
- For each entity set and relationship set there is a unique schema that is assigned the name of the corresponding entity set or relationship set.
- Each schema has a number of columns (generally corresponding to attributes),
 which have unique names.
- Specification of domain (data types) for each column is optional but will be required in the data definition

Representing Entity Sets

- A strong entity set reduces to a schema with the same attributes student(<u>ID</u>, name, tot_cred)
- A weak entity set becomes a table that includes a column for the primary key of the identifying strong entity set

section (course id, sec id, sem, year)

Example

Representation of Entity Sets with Composite Attributes

instructor

```
ID
name
  first_name
   middle_initial
   last name
address
   street
     street_number
      street name
     apt number
   city
   state
   zip
{ phone_number }
date_of_birth
age()
```

- Composite attributes are flattened out by creating a separate attribute for each component attribute
 - Example: given entity set instructor with composite attribute name with component attributes first_name and last_name the schema corresponding to the entity set has two attributes name_first_name and name_last_name
 - Prefix omitted if there is no ambiguity (name_first_name could be first_name)
- Ignoring multivalued attributes, extended instructor schema is

```
    instructor(ID,
first_name, middle_initial, last_name,
street_number, street_name,
apt_number, city, state, zip_code,
date_of_birth)
```

Representation of Entity Sets with Multivalued Attributes

- A multivalued attribute M of an entity E is represented by a separate schema EM
- Schema EM has attributes corresponding to the primary key of E and an attribute corresponding to multivalued attribute M
- Example: Multivalued attribute phone_number of instructor is represented by a schema:

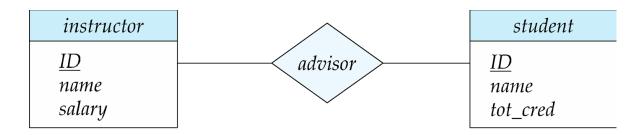

```
inst_phone= ( ID, phone number)
```

- Each value of the multivalued attribute maps to a separate tuple of the relation on schema EM
 - For example, an *instructor* entity with primary key 22222 and phone numbers 456-7890 and 123-4567 maps to two tuples: (22222, 456-7890) and (22222, 123-4567)

Representing Relationship Sets

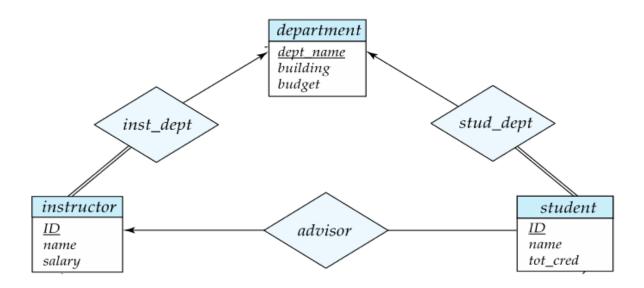

- A many-to-many relationship set is represented as a schema with attributes for the primary keys of the two participating entity sets, and any descriptive attributes of the relationship set.
- Example: schema for relationship set *advisor*

$$advisor = (s id, i id)$$

Redundancy of Schemas

- Many-to-one and one-to-many relationship sets that are total on the many-side can be represented by adding an extra attribute to the "many" side, containing the primary key of the "one" side
- Example: Instead of creating a schema for relationship set inst_dept, add an attribute dept_name to the schema arising from entity set instructor
- Example

Redundancy of Schemas (Cont.)

- For one-to-one relationship sets, either side can be chosen to act as the "many" side
 - That is, an extra attribute can be added to either of the tables corresponding to the two entity sets
- If participation is partial on the "many" side, replacing a schema by an extra attribute in the schema corresponding to the "many" side could result in null values

Redundancy of Schemas (Cont.)

- The schema corresponding to a relationship set linking a weak entity set to its identifying strong entity set is redundant.
- Example: The section schema already contains the attributes that would appear in the sec_course schema

Specialization and Generalization

- **Top-down design process**; we designate sub-groupings within an entity set that are distinctive from other entities in the set.
 - These sub-groupings become lower-level entity sets that have attributes or participate in relationships that do not apply to the higher-level entity set.
 - Depicted by a triangle component labeled ISA (e.g., instructor "is a" person).
 - Attribute inheritance a lower-level entity set inherits all the attributes and relationship participation of the higher-level entity set to which it is linked.
- A bottom-up design process combine a number of entity sets that share the same features into a higher-level entity set.
 - Specialization and generalization are simple inversions of each other; they are represented in an E-R diagram in the same way.
 - The terms specialization and generalization are used interchangeably.

Specialization Example

- Overlapping employee and student
- **Disjoint** *instructor* and *secretary*
- Total and partial

Representing Specialization via Schemas

- Method 1:
 - Form a schema for the higher-level entity
 - Form a schema for each lower-level entity set, include primary key of higher-level entity set and local attributes

schema	attributes
person	ID, name, street, city
student	ID, tot_cred
employee	ID, salary

 Drawback: getting information about, an employee requires accessing two relations, the one corresponding to the low-level schema and the one corresponding to the high-level schema

Representing Specialization as Schemas (Cont.)

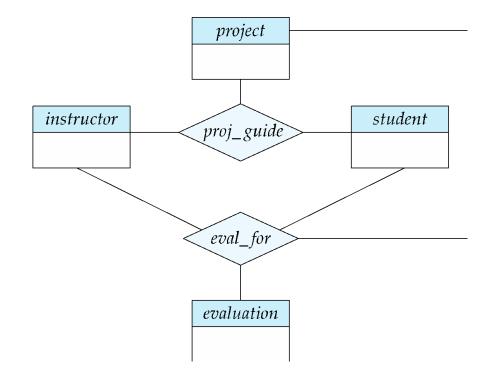

- Method 2:
 - Form a schema for each entity set with all local and inherited attributes

schema	attributes
person	ID, name, street, city
student	ID, name, street, city, tot_cred
employee	ID, name, street, city, salary

 Drawback: name, street and city may be stored redundantly for people who are both students and employees

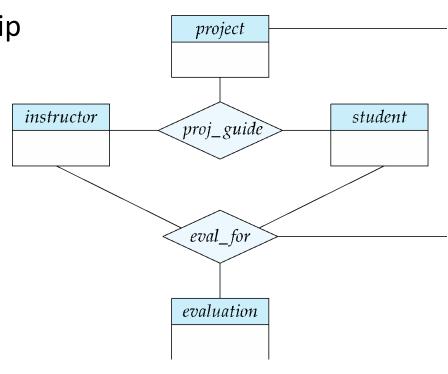

Aggregation

- Consider the ternary relationship proj_guide, which we saw earlier
- Suppose we want to record evaluations of a student by a guide on a project

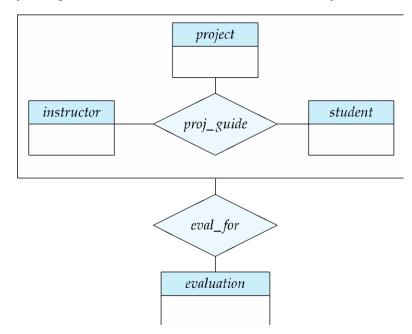

Aggregation (Cont.)

- Relationship sets *eval_for* and *proj_guide* represent overlapping information
 - Every eval_for relationship corresponds to a proj_guide relationship
 - However, some proj_guide relationships may not correspond to any eval_for relationships
 - So we can't discard the proj_guide relationship
- Eliminate this redundancy via aggregation
 - Treat relationship as an abstract entity
 - Allows relationships between relationships
 - Abstraction of relationship into new entity

Aggregation (Cont.)

- Eliminate this redundancy via aggregation without introducing redundancy, the following diagram represents:
 - A student is guided by a particular instructor on a particular project
 - A student, instructor, project combination may have an associated evaluation

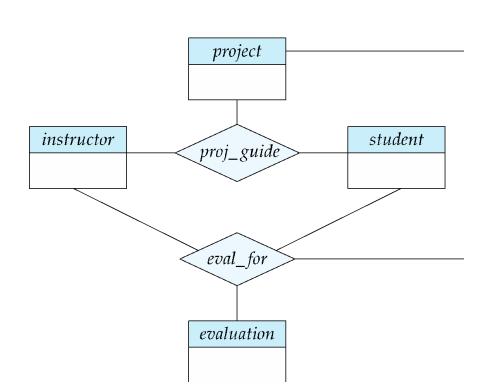

Reduction to Relational Schemas

- To represent aggregation, create a schema containing
 - Primary key of the aggregated relationship,
 - The primary key of the associated entity set
 - Any descriptive attributes
- In our example:

The schema eval_for is:

eval_for (s_ID, project_id, i_ID, evaluation_id)

The schema *proj_guide* is redundant.

Relational Operations

Relational Operations

- Order of tuples is irrelevant (tuples may be stored in an arbitrary order)
- The special value null is a member of every domain. Indicated that the value is "unknown"
 - The null value causes complications in the definition of many operations
- Relational operations take one or two relations as input and produce a new relation as their result.
- Six basic operations and corresponding operators in Relational Algebra
 - select: σ
 - project: ∏
 - union: U
 - set difference: –
 - Cartesian product: x
 - rename: *ρ*

Select Operation

- The select operation selects tuples that satisfy a given predicate.
- Notation: $\sigma_p(r)$, p is called the **selection predicate**
- Example: select those tuples of the *instructor* relation where the instructor is in the "Physics" department.
 - Query $\sigma_{dept\ name="Physics"}$ (instructor)
 - Result

ID	name	dept_name	salary
22222	Einstein	Physics	95000
33456	Gold	Physics	87000

Select Operation (Cont.)

- We allow comparisons using =, \neq , >, \geq . <. \leq in the selection predicate.
- We can combine several predicates into a larger predicate by using the connectives:

$$\land$$
 (and), \lor (or), \neg (not)

- Example: Find the instructors in Physics with a salary greater \$90,000, we write: $\sigma_{dept\ name="Physics"} \Lambda_{salary > 90,000}$ (instructor)
- The select predicate may include comparisons between two attributes.
 - Example, find all departments whose name is the same as their building name:
 - σ_{dept name=building} (department)

Project Operation

- A unary operation that returns its argument relation, with certain attributes left out.
- Notation:

$$\prod_{A1,A2,A3...Ak} (r)$$

where A_1 , A_2 , ..., A_k are attribute names and r is a relation name.

- The result is defined as the relation of k columns obtained by erasing the columns that are not listed
- Duplicate rows removed from result, since relations are sets

Project Operation Example

- Example: eliminate the *dept_name* attribute of *instructor*
- Query: $\prod_{ID, name, salary}$ (instructor)
- Result:

name	salary
Srinivasan	65000
Wu	90000
Mozart	40000
Einstein	95000
El Said	60000
Gold	87000
Katz	75000
Califieri	62000
Singh	80000
Crick	72000
Brandt	92000
Kim	80000
	Srinivasan Wu Mozart Einstein El Said Gold Katz Califieri Singh Crick Brandt

Composition of Relational Operations

- The result of a relational operation is relation and therefore of operations can be composed together into a single expression.
- Consider the query -- Find the names of all instructors in the Physics department.

$$\prod_{name} (\sigma_{dept\ name\ ="Physics"} (instructor))$$

• Instead of giving the name of a relation as the argument of the projection operation, we give an expression that evaluates to a relation.

Cartesian-Product Operation

To combine information from any two relations. Denoted by X
instructor X teaches

- Since the instructor *ID* appears in both relations we distinguish between these attribute by attaching to the attribute the name of the relation from which the attribute originally came.
 - instructor.ID
 - teaches.ID

The instructor x teaches table

instructor.ID	name	dept_name	salary	teaches.ID	course_id	sec_id	semester	year

Join Operation

The Cartesian-Product

instructor X teaches

associates every tuple of instructor with every tuple of teaches.

• To get only those tuples of "instructor X teaches" that pertain to instructors and the courses that they taught, we write:

 $\sigma_{instructor,id} = teaches,id$ (instructor x teaches))

Join Operation (Cont.)

• The table corresponding to:

σ instructor.id = teaches.id (instructor x teaches))

instructor.ID	name	dept_name	salary	teaches.ID	course_id	sec_id	semester	year
10101	Srinivasan	Comp. Sci.	65000	10101	CS-101	1	Fall	2017

Join Operation (θ-join)

- The **join** operation allows us to combine a select operation and a Cartesian-Product operation into a single operation.
- Consider relations r and s
- Let "theta" be a predicate on attributes in the schema r "union" s. The join operation
 r ⋈_θ s is defined as follows:

$$r \bowtie_{\theta} s = \sigma_{\theta} (r \times s)$$

Thus

σ_{instructor.id = teaches.id} (instructor x teaches)
 can equivalently be written as
 instructor ⋈ _{Instructor.id = teaches.id} teaches.

• If θ has the equality operator, it is called **equijoin**

Natural Join

- Natural join (⋈) is a binary operator that is written as (r ⋈ s) where r and s are relations.
- The result of the natural join is the set of all combinations of tuples in r and s that are equal on their common attribute names.

Union Operation

- To combine two relations. Notation: r U s
- For r U s to be valid.
 - 1. *r*, *s* must have the *same* **arity** (same number of attributes)
 - 2. The attribute domains must be **compatible** (example: 2^{nd} column of r deals with the same type of values as does the 2^{nd} column of s)

Example: to find all courses taught in the Fall 2017 semester, or in the Spring 2018 semester, or in both

 $\prod_{course\ id} (\sigma_{semester="Fall"\ \Lambda\ year=2017}(section)) \cup \prod_{course\ id} (\sigma_{semester="Spring"\ \Lambda\ year=2018}(section))$

Union Operation (Cont.)

• Result of:

 $\prod_{course\ id} (\sigma_{semester="Fall"\ \Lambda\ year=2017}(section)) \cup \prod_{course\ id} (\sigma_{semester="Spring"\ \Lambda\ year=2018}(section))$

course_id

CS-319

CS-347

FIN-201

HIS-351

MU-199

PHY-101

Set-Intersection Operation

- To find tuples that are in both the input relations. Notation: $r \cap s$
- Assume:
 - r, s have the same arity
 - attributes of *r* and *s* are compatible
- Example: Find the set of all courses taught in both the Fall 2017 and the Spring 2018 semesters.

$$\prod_{course_id} (\sigma_{semester="Fall" \land year=2017}(section)) \cap \prod_{course_id} (\sigma_{semester="Spring" \land year=2018}(section))$$

Result

course_id
CS-101

Set Difference Operation

- To find tuples that are in one relation but are not in another. Notation r-s
- Set differences must be taken between compatible relations.
 - r and s must have the same arity
 - attribute domains of *r* and *s* must be compatible
- Example: to find all courses taught in the Fall 2017 semester, but not in the Spring 2018 semester

$$\prod_{course_id} (\sigma_{semester="Fall" \land year=2017}(section)) - \prod_{course_id} (\sigma_{semester="Spring" \land year=2018}(section))$$

course_id

CS-347

PHY-101

The Assignment Operation

- Creates temporary relations.
- Denoted by ← and works like assignment in a programming language.
- Example: Find all instructor in the "Physics" and Music department.

```
Physics \leftarrow \sigma_{dept\_name="Physics"} (instructor)

Music \leftarrow \sigma_{dept\_name="Music"} (instructor)

Physics \cup Music
```

The Rename Operation

- The results of relational expressions do not have a name that we can use to refer to them. The rename operator, ρ , is provided for that purpose
- The expression:

$$\rho_{x}(E)$$

returns the result of expression E under the name x

Another form of the rename operation:

$$\rho_{x(A1,A2,\ldots An)}(E)$$

Equivalent Queries

- There is more than one way to write a query
- Example: Find information about courses taught by instructors in the Physics department with salary greater than 90,000
- Query 1

$$\sigma_{dept_name="Physics"} \wedge_{salary > 90,000} (instructor)$$

Query 2

$$\sigma_{dept\ name="Physics"}(\sigma_{salary>90.000}(instructor))$$

• The two queries are not identical; they are, however, equivalent -- they give the same result on any database.

Equivalent Queries

- There is more than one way to write a query in relational algebra.
- Example: Find information about courses taught by instructors in the Physics department
- Query 1

```
\sigma_{dept\_name= "Physics"} (instructor \bowtie_{instructor.ID= teaches.ID} teaches)
```

Query 2

$$(\sigma_{dept_name= "Physics"}(instructor)) \bowtie_{instructor.ID= teaches.ID} teaches$$

 The two queries are not identical; they are, however, equivalent -- they give the same result on any database.
